

INSECTICIDAL 3-(2,6-DISUBSTITUTED PHENYL)-5-
[5-ARYLTHIEN-2-YL]-1,2,4-TRIAZOLES

Background of the Invention

5 This application is a division of application Serial No. 10/244,124 filed on September 13, 2002. This application claims the benefit of U.S. Provisional Application Number 60/322,236, filed September 14, 2001.

10 The present invention concerns novel 3-(2,6-disubstituted phenyl)-5-(4- or 5-arylthien-2- or -3-yl)-1,2,4-triazoles and their use in controlling lepidoptera, coleoptera, mites and other sucking pests. This invention also includes new synthetic procedures, intermediates for preparing the compounds, pesticide compositions containing the compounds, and methods of controlling lepidoptera, coleoptera, mites and sucking pests using the compounds.

15 There is an acute need for new insecticides and acaricides. Insects and mites are developing resistance to the insecticides and acaricides in current use. At least 400 species of arthropods are resistant to one or more insecticides. The development of resistance to some of the older insecticides, such as DDT, the carbamates, and the organophosphates, is well known. But resistance has even developed to some of the newer pyrethroid insecticides and acaricides. Therefore a need exists for new insecticides and acaricides, and particularly for compounds that have new or atypical modes of action.

20 A number of 3,5-diphenyl-1*H*-1,2,4-triazole derivatives have been described in the literature as having acaricidal activity (U.S. Patent 5,482,951; JP 8092224, EP 572142, JP 08283261). U.S. Patent 6,015,826 discloses certain 3-(substituted phenyl)-5-(thienyl)-1,2,4-triazoles and their use in controlling certain insects and mites, viz., aphids, mites and whiteflies. The present invention provides novel compounds with broad-spectrum activity against lepidoptera and coleoptera in addition to mites and other sucking pests.

Insecticide and Miticide Utility

The compounds of the invention are useful for the control of insects and mites. Therefore, the present invention also is directed to a method for inhibiting an insect or mite which comprises applying to a locus of the insect or mite an insect- or mite-inhibiting amount of a compound of formula (1).

The compounds are useful for reducing populations of insects and mites and are useful in a method of inhibiting an insect or mite population which comprises applying to a locus of the insect or mite an effective insect- or mite-inactivating amount of a compound of formula (1). The "locus" of insects or mites is a term used herein to refer to the environment in which the insects or mites live or where their eggs are present, including the air surrounding them, the food they eat, or objects which they contact. For example, insects or mites which eat or contact edible or ornamental plants can be controlled by applying the active compound to plant parts such as the seed, seedling, or cutting which is planted,

- the leaves, stems, fruits, grain, or roots, or to the soil in which the roots are growing . It is contemplated that the compounds might also be useful to protect textiles, paper, stored grain, seeds, domesticated animals, buildings or human beings by applying an active compound to or near such objects. The term
- 5 "inhibiting an insect or mite" refers to a decrease in the numbers of living insects or mites, or a decrease in the number of viable insect or mite eggs. The extent of reduction accomplished by a compound depends, of course, upon the application rate of the compound, the particular compound used, and the target insect or mite species. At least an inactivating amount should be used. The terms "insect-
- 10 inactivating amount" and "mite-inactivating amount" are used to describe the amount, which is sufficient to cause a measurable reduction in the treated insect or mite population. Generally an amount in the range from about 1 to about 1000 ppm by weight active compound is used. For example, insects and mites which can be inhibited include, but are not limited to:

Insecticidal test for tobacco budworm (*Heliothis virescens*), beet armyworm (*Spodoptera exigua*), and cabbage looper (*Trichoplusia ni*).

To prepare test solution, the test compound was formulated at 400 ppm in 7.5 mL of 2 acetone:1 tap water. 250 µL of the test solution was pipetted upon the surface of 8 mL of lepidopteran diet (modified Shorey) contained in each of five one-ounce plastic cups (one cup = 1 replication). A second-instar beet armyworm was placed upon the treated diet in each cup once the solvent had air-dried. The solutions remaining after completing applications to the one-ounce cups were then used as leaf-dip solutions for 3.5 cm leaf discs cut from cabbage leaves and cotton cotyledons. Five discs of each type of plant were dipped until thoroughly coated into each rate of each compound (= 5 replications of each treatment). After air-drying, the treated leaf discs were placed individually into one-ounce plastic cups. Each dried, treated cotton cotyledon disc was infested with a 2nd instar tobacco budworm larva, and each cabbage leaf disc was infested with a 2nd instar cabbage looper larva. Cups containing the treated substrates and larvae were capped and then held in a growth chamber at 25 °C, 50-55% RH, and 14 hr light:10 hr dark for 5 days. The number of dead insects of 5 per species per treatment was then determined and the results are given in Tables 1-4.

Insecticidal test for cotton aphid (*Aphis gossypii*)

To prepare spray solutions, 1 mg of each test compound was dissolved into 1 mL of a 90:10 acetone:ethanol solvent. This 1 mL of chemical solution was added to 19 mL of water containing 0.05% Tween 20 surfactant to produce a 50 ppm spray solution.

Squash cotyledons were infested with cotton aphid (all life stages) 16-20 hours prior to application of spray solution. The solution was sprayed on both

sides of each infested squash cotyledon (0.5 mL X 2 each side) with a sweeping action until runoff. The plants were allowed to air dry and held for 3 days in a controlled room at 26 °C and 40% RH after which time the test was graded. Grading was by actual count using a dissecting microscope and comparison of test counts to the untreated check. Results are given in Tables 1-4 as percent control based on population reduction versus the untreated.

Insecticidal test for two-spotted spider mite (*Tetranychus urticae*)

Ovicide Method:

Ten adult female two-spotted spider mites were placed on eight 2.2 cm leaf discs of cotton leaf, allowed to oviposit over 24 hours, and thereafter removed. The leaf discs were sprayed with 100 ppm test solutions using a hand syringe, then allowed to dry with sixteen discs left untreated as a negative control. Discs were placed on an agar substrate and held at 24 °C and 90% RH for 6 days. Percent control based on the number of hatched larvae on treated discs and the number on untreated discs is reported in Tables 1-4.

Insecticidal test for Sweetpotato Whitefly (*Bemisia tabacia*)

Four mg of each test compound was dissolved by adding 4 mL of a 90:10 acetone:ethanol solvent mixture to the vial containing the sample compound. This solution was added to 16 mL of water containing 0.05% Tween 20 surfactant to produce 20 mL of an 200 ppm spray solution.

Five-week-old cotton plants reared in a greenhouse were stripped of all foliage except for the two uppermost true leaves that were greater than 5 cm in diameter. These plants were then placed into a laboratory colony of whiteflies for two days for oviposition by the colony females. All whiteflies were then removed from the test plants with pressurized air. The spray solution was then applied to

the test plants with a hand-held syringe fitted with hollow cone nozzle. One mL spray solution was applied to each leaf top and bottom for a total of 4 mL per plant. Four replications of each test compound utilized a total of 16 mL spray solution. Plants were air dried and then placed in a holding chamber (28 °C and 5 60% RH) for 13 days. Compound efficacy was evaluated by counting, under an illuminated magnifying glass, the number of large nymphs (3rd-4th instar) per leaf.

Percent control based on reduction of large nymphs of a test compound compared to solution-only (no test compound) sprayed plants is reported in Tables 10 1-4.

Compositions

The compounds of this invention are applied in the form of compositions which are important embodiments of the invention, and which comprise a compound of this invention and a phytologically-acceptable inert carrier. The 15 compositions are either concentrated formulations which are dispersed in water for application, or are dust or granular formulations which are applied without further treatment. The compositions are prepared according to procedures and formulae which are conventional in the agricultural chemical art, but which are novel and important because of the presence therein of the compounds of this 20 invention. Some description of the formulation of the compositions will be given, however, to assure that agricultural chemists can readily prepare any desired composition.

The dispersions in which the compounds are applied are most often aqueous suspensions or emulsions prepared from concentrated formulations of the 25 compounds. Such water-soluble, water-suspendable or emulsifiable formulations are either solids, usually known as wettable powders, or liquids usually known as

emulsifiable concentrates or aqueous suspensions. Wettable powders, which may be compacted to form water dispersible granules, comprise an intimate mixture of the active compound, an inert carrier, and surfactants. The concentration of the active compound is usually from about 10% to about 90% by weight. The inert
5 carrier is usually chosen from among the attapulgite clays, the montmorillonite clays, the diatomaceous earths, or the purified silicates. Effective surfactants, comprising from about 0.5% to about 10% of the wettable powder, are found among the sulfonated lignins, the condensed naphthalenesulfonates, the naphthalenesulfonates, the alkylbenzenesulfonates, the alkyl sulfates, and
10 nonionic surfactants such as ethylene oxide adducts of alkyl phenols.

Emulsifiable concentrates of the compounds comprise a convenient concentration of a compound, such as from about 50 to about 500 grams per liter of liquid, equivalent to about 10% to about 50%, dissolved in an inert carrier which is either a water miscible solvent or a mixture of water-immiscible organic
15 solvent and emulsifiers. Useful organic solvents include aromatics, especially the xylenes, and the petroleum fractions, especially the high-boiling naphthalenic and olefinic portions of petroleum such as heavy aromatic naphtha. Other organic solvents may also be used, such as the terpenic solvents including rosin derivatives, aliphatic ketones such as cyclohexanone, and complex alcohols such
20 as 2-ethoxyethanol. Suitable emulsifiers for emulsifiable concentrates are chosen from conventional nonionic surfactants, such as those discussed above.

Aqueous suspensions comprise suspensions of water-insoluble compounds of this invention, dispersed in an aqueous vehicle at a concentration in the range from about 5% to about 50% by weight. Suspensions are prepared by finely
25 grinding the compound, and vigorously mixing it into a vehicle comprised of water and surfactants chosen from the same types discussed above. Inert ingredients, such as inorganic salts and synthetic or natural gums, may also be

added, to increase the density and viscosity of the aqueous vehicle. It is often most effective to grind and mix the compound at the same time by preparing the aqueous mixture, and homogenizing it in an implement such as a sand mill, ball mill, or piston-type homogenizer.

5 The compounds may also be applied as granular compositions, which are particularly useful for applications to the soil. Granular compositions usually contain from about 0.5% to about 10% by weight of the compound, dispersed in an inert carrier which consists entirely or in large part of clay or a similar inexpensive substance. Such compositions are usually prepared by dissolving the
10 compound in a suitable solvent and applying it to a granular carrier which has been pre-formed to the appropriate particle size, in the range of from about 0.5 to 3 mm. Such compositions may also be formulated by making a dough or paste of the carrier and compound and crushing and drying to obtain the desired granular particle size.

15 Dusts containing the compounds are prepared simply by intimately mixing the compound in powdered form with a suitable dusty agricultural carrier, such as kaolin clay, ground volcanic rock, and the like. Dusts can suitably contain from about 1% to about 10% of the compound.

20 It is equally practical, when desirable for any reason, to apply the compound in the form of a solution in an appropriate organic solvent, usually a bland petroleum oil, such as the spray oils, which are widely used in agricultural chemistry.

25 Insecticides and acaricides are generally applied in the form of a dispersion of the active ingredient in a liquid carrier. It is conventional to refer to application rates in terms of the concentration of active ingredient in the carrier. The most widely used carrier is water.

The compounds of the invention can also be applied in the form of an aerosol composition. In such compositions the active compound is dissolved or dispersed in an inert carrier, which is a pressure-generating propellant mixture. The aerosol composition is packaged in a container from which the mixture is
5 dispensed through an atomizing valve. Propellant mixtures comprise either low-boiling halocarbons, which may be mixed with organic solvents, or aqueous suspensions pressurized with inert gases or gaseous hydrocarbons.

The actual amount of compound to be applied to loci of insects and mites is not critical and can readily be determined by those skilled in the art in view of
10 the examples above. In general, concentrations from 10 ppm to 5000 ppm by weight of compound are expected to provide good control. With many of the compounds, concentrations from 100 to 1500 ppm will suffice.

The locus to which a compound is applied can be any locus inhabited by an insect or mite, for example, vegetable crops, fruit and nut trees, grape vines,
15 ornamental plants, domesticated animals, the interior or exterior surfaces of buildings, and the soil around buildings.

Because of the unique ability of insect and mite eggs to resist toxicant action, repeated applications may be desirable to control newly emerged larvae, as
20 is true of other known insecticides and acaricides.
